Title of the invention: DATA TRANSFER METHOD, APPARATUS,
2 AND RECORDING MEDIUM FOR USE IN HIERARCHICAL SYSTEM

Background of the Invention

4 The present invention relates generally to a data
transfer method, a data transfer apparatus, and data
6 recording medium for use in hierarchical systems.

[Referring to] FIG. 1, there is shown^{shows} a system in
6 which a managed system returns static information (namely,
unique information having little change in result)^{in response} to a
10 requirement by a manager system for information acquisition.
To be more specific, an information acquisition requirement
by a manager system (101) is sent to a managed system (106)
through submanager systems (102 through 105) in a relay
manner.

Likewise, a response result to the information
acquisition requirement is also returned to the manager
system through the submanager systems in a relay manner.
At this time, an information acquisition requirement and
its response result are not transferred over different
routes.

Referring to FIG. 2, each of the submanager systems
(202 through 205) is composed of a manager capability and a
submanager capability and may issue an information
acquisition requirement like the manager system, performing
the same information acquisition requirement operation as

with the case of the manager system. One example of a
2 system having the above-mentioned characteristics is a
system in a hierarchical configuration for acquiring [the]
4 property information on a submanager system from a manager
system as shown in FIG. 3.

6 Summary of the invention

If a manager system and submanager systems issue (a) ^{the}
8 same information acquisition requirement to a managed
system, the same information acquisition requirement and
10 its reply result flow on a route multiple times, causing ^a
redundancy (in the portions in which the arrows of
12 information acquisition requirement and its replay result
overlap as shown in FIG. 1), [and] sometimes overloading the
14 network.

In order to solve the above-mentioned problems, the
16 present invention executes the following ^{procedure} [means]. If an
information acquisition requirement is made from the
20 manager system to a managed system, it is determined in the
submanager systems on the ^{the} routes to that managed system
22 whether or not to issue (a) same information acquisition
requirement.

If the same information acquisition requirement is
to be issued, it is recognized in advance in the submanager
systems. When the information acquisition requirement was
received by the managed system and it has returned a

response result, the submanager systems acquire the
2 response result if it is necessary, and pass the response
result to the manager system.

4 This configuration can prevent ^{the} same data from
flowing over a route in a duplicated, redundant manner. In
6 addition, by having each submanager system store in advance
the response results for particular information acquisition
8 requirements, the submanager system can pass the stored ^{result in}
response (result) to a particular information acquisition
10 requirement to the manager system or a submanager system in
an upper layer that issued the requirement. Consequently,
12 this configuration reduces the data traffic on the route
from that submanager system to the managed system.

14 Brief description of the drawings

^{better understood} These and other objects of the invention will be
16 ^{following} (seen) by reference to the ^{following} description, taken in connection
with the accompanying drawing, in which:

18 FIG. 1 is a diagram illustrating the configuration
of a system to which the present invention is applicable
20 and the flows of data transfer; ^{therein}

FIG. 2 is a diagram illustrating the configuration
22 of a system ^{of the type} to which the present invention is applicable;

FIG. 3 is a diagram illustrating one example of a
system configuration for managing property information in a
multi-layer system;

FIG. 4 is a diagram illustrating a state in which each of the manager system and submanager systems has items;

FIG. 5 is a diagram illustrating a method of merging items in each of the manager system and submanager systems;

FIG. 6 is a diagram illustrating a method of updating property information in each of the manager system and submanager systems;

FIG. 7 is a diagram illustrating the structure of a DB having attributes;

FIG. 8 is a diagram illustrating the configuration of a program in the manager system;

FIG. 9 is a diagram illustrating one example of the item edit screen in the manager system;

FIG. 10 is a flowchart indicative of item editing;

FIG. 22 is a diagram illustrating a state in which items are initialized;

FIG. 23 is a diagram illustrating a state in which items are merged;

FIG. 24 is a flowchart indicative of the merge processing;

FIG. 25 is a diagram illustrating a state in which property information is updated;

FIG. 26 is a flowchart indicative of the update processing;

FIG. 27 is a diagram illustrating a state in which items are initialized;

FIG. 28 is a diagram illustrating a state in which items are merged; and

FIG. 29 is a diagram illustrating a state in which property information is updated.

Detailed description of preferred embodiments

2 This invention will be described in further detail
by way of example with reference to the accompanying
4 drawings. For embodiments of the invention, systems are
used, for example, for managing the property information of
6 managed systems in a multilayer network environment as
shown in FIG. 3 (although not shown in FIG. 3, business
8 hubs such as business offices, branches, and sales offices
and the departments in each of these hubs also have
10 multiple submanager systems and managed systems). It is
assumed here that the submanager systems in the multilayer
12 network environment ^{are} subordinate to the manager system,
and the submanager systems in every ^{layer do} [layers does] not depend
14 on the information about the other submanager systems in
that layer. The following ^{description provides an outline of} [outlines] the flow of processing.

16 Now, referring to FIG. 4, the items of information
required by the manager system and the submanager systems
18 in every ^{layer} [layers] are defined. Next, as shown in FIG. 5, the
manager system issues an information acquisition
20 requirement, and by ^{repeated} [repeating the] merging of the items of
required information and downloading item files in the
22 submanager systems, the manager system requires information
from the managed system.

24 Referring to FIG. 6, a file containing the result of
property information inputted in the managed system is
uploaded into the manager system through the submanager

systems. In the course of this uploading, each submanager
✓ system updates the information with respect to the items
defined by itself and uploads the other items to the upper
✓ submanager system.

It should be noted that the embodiments are ^{directed to} property
✓ information managing systems as described above, but the
present invention is also applicable to systems that handle
✓ other kinds of information to be required for acquisition.

Embodiment 1:

10 [Referring to] FIG. 8[there] is [shown] a block diagram
of the program in each submanager system. The submanager
12 system comprises a main manager program (802), a merge
processing block (hereafter referred to as merge-process)
14 (805) that receives an item file composed of item groups
downloaded from the upper-layer manager system and merges
18 the received items, an update processing block (hereafter
referred to as update-process) (804) that receives a result
20 file composed of the items and property information from
the lower-layer system (the lower-layer manager system or
22 the managed system) and updates the property information,
an edit processing block (hereafter referred to as edit-
24 process) (803) that edits items managed in its own system,
a user terminal (801) on which information display and
26 ^{operations} [operation] are executed, and a DB (Database) (806) storing
the items and property information. The structure of the
DB is as shown in FIG. 7 in which each item has an

attribute field.

2 To this attribute field, one of three statuses is
set: "0"^{identifies} an item managed by the system in a current layer
4 (hereafter also referred to as "this system") indicative
that the item is managed in the layer of this current
6 system; "1"^{identifies} an item managed by^{an} upper system indicative that
the item is managed by the upper system; and "2"^{identifies} a common
8 item indicative that this item is common to this system and
the upper system. Basically, the submanager system in each
10 layer can be realized by [the similar]^a configuration^{similar} to that
of the submanager systems in the other layers. However,
12 the program of the manager system at the top of the
multilayer environment has no merge-process.

14 All the processing operations mentioned above can be
executed (in) concurrently. In the concurrent processing,
16 there is a time in which DB update-processes overlap. It
is assumed that this portion of overlapped time is
18 exclusively controlled in advance (this, however, is
omitted from the description of the processing flow below).

20 First,^{the} edit-process^{will be} (is) described. In edit-process,
the contents of the DB of this system are displayed and
22 edited. For displaying the property information stored in
the DB, only [the] items other than those managed by the
24 upper system are displayed.

The output of edit-process can also be directed to a
file or a printer in a free form in addition to the display

device of the user terminal. In edit-process, addition and
2 deletion of items and ^{an} attribute change of items can be
performed. FIG. 9 shows one example of the edit screen.
4 FIGS. 10 and 11 show flowcharts indicative of the edit
operation. A list of items and their attributes are
6 displayed on the display device of the user terminal (S301),
and the system ^{will} wait for an input operation by the user
8 (S302).

When the edit operation has been completed and the
10 end thereof is instructed by the user (S303), this system
extracts the items from the DB of this system and downloads
12 the item file containing the extracted items to the lower
submanager system or the managed system ^{directly} (directed) connected
14 to this system (S304), ^{at time} (upon) which the editing is ended. If
no editing has been performed, the file downloading is not
16 performed. If the addition of an item is instructed (S305),
this system adds the specified item to its DB, specifies
18 the attribute of the added item as the item managed by this
system ("0") (S306), and waits for another operation to be
19 inputted by the user (S302). If the deletion of an item is
instructed (S307), this system deletes the specified item
22 from its DB directly, provided that the attribute of the
item to be deleted is the item managed by this system ("0")
24 (the property information is also deleted if it is set for
the item) (S309). If the attribute is the item managed by ^{the} a
26 upper system ("1"), this system outputs an error message

(S311). If the attribute is the common item ("2"), this
2 system changes the attributes to the item managed by ^{the} upper
system ("1") (S310).

4 When the above-mentioned processing has been
completed, this system waits for an operation to be
6 inputted by the user (S302). If the change of an item
attribute is instructed (S312), the attribute of that item
8 is changed from the item managed by ^{the} upper system ("1") to
the common item ("2"), or if the instruction is vice verse,
10 the attribute of that item is changed (S314) from the
common item ("2") to the item managed by ^{the} upper system ("1"),
12 outputs ^{an} error message (S315) and waits for ^{an} operation to be
inputted by the user.
14 ^{In the case of} (Where) other ^{instructions} (instruction other) than those stated
above, this system outputs ^{an} error message (S316) and waits
16 for ^{an} operation to be inputted by the user (S302). It is
practicable to determine particular button operations that
18 will cause an error and deactivate the buttons concerned in
advance to prevent the user from operating them.

20 The following describes ^a merge-process with reference
to the transition diagrams shown in FIGS. 12 through 14 and
the flowchart shown in FIG. 15. It is assumed that merge-
process is performed in a lower manager system shown in the
transition diagrams. In the initial state, this manager
system is waiting for the downloading of data from the
upper manager system or the manager system (S001). At this

moment, the items in the DBs of the upper and lower manager
2 systems are as shown in FIG. 12.

It should be noted that, for the convenience of
4 description, the items from the upper manager system have
already been prepared in the lower manager system (items A
6 through C and F).

First, when an item file has been downloaded from
8 the upper manager system, this lower manager system deletes
all items having the attribute of the item managed by upper
10 system ("1") (S002). Next, this system changes the common
item ("0") to the item managed by this system ("0") (S003).
12 The states of the items in the DBs of the upper and lower
manager systems are shown in FIG. 13.

14 Then, this lower manager system opens the downloaded
item file (1304) and reads the items (S004). When all
16 items have been read from the item file (S005), this system
prepares an item file containing the extracted item data
18 from its own DB and downloads the prepared item file to the
directly connected submanager system or managed system
20 (S008) in ^alower layer and waits for another downloading
operation (S008 to S001).

22 This submanager system reads the items one by one in
the item file (1304) and checks its own DB for ^{the} (any) same
24 item (S006). If the same item is found, this system
updates its DB by changing the attribute of the same item
to the common item ("2") and starts reading the next items

(S009 to S004). If there is no same item, this system adds
2 the read items to its DB and sets the attribute of the read
item to the item managed by ^{an} upper system ("1") and starts
4 reading the next items (S007 to S004).

FIG. 14 shows one example of the DB update operation
6 performed in accordance with the flowchart of merge-process.
As shown, item A, item B, and item C are downloaded to this
8 system (lower manager system) from its upper manager system
to be merged with item C, item D, and item E held in this
10 system, the result of merge-process being displayed in the
after-change table. Then, item C through item B are
12 downloaded to the system in ^a further lower layer connected
to this system.

^{the}
14 The following describes ^{the} update-process with
reference to the transition diagrams shown in FIGS. 14 and
16 16 and the flowchart shown in FIG. 17. In the initial
state, this system is waiting for the uploading of a result
18 file from its lower-layer system (S101). The state of the
items of the DB of this system is as shown in the after-
20 change table shown in FIG. 14.

First, this system opens the uploaded result file 1
72 (1606) and reads the items and property information
contained in the file (S102). Next, this system searches
24 its DB for the read item. If the attribute of the detected
item is the item managed by ^{an} upper system ("1") (S104), then
this system writes the item and the property information in

the result file 1 to a result file 2 (1605) to upload it to
the upper manager system (S105) and starts reading^{the} next
item and property information (S102). If the attribute of
the detected item is other than the item managed by^{the} upper
system ("1") (S104), this system updates the property
information of the item concerned in the DB of this system
(S107).

8 If the attribute of the detected item is the common
item ("2") (S108), this system writes the item and property
10 information in the result file 1 (1606) to the result file
2 (1605) to upload it to its upper manager system and
12 starts reading^{the} next item and property information (S102).
When this system has read all items and property
14 information, it uploads the prepared result file 2 (1605)
to the upper manager system (S106) and then waits again for
16 the uploading of the result file 1 (1606) from the lower-
layer system (S101).

18 At this moment, the state of the DB is as shown in
FIG. 16. FIG. 16 shows that the property information about
20 item C, item D, and item E of the result file 1 (1606) are
reflected on the DB, and item A, item B, and item C have
22 been uploaded to the upper system.

Because the attribute of item C is the common item,
24 it is reflected (updated) on the DB and uploaded to the
upper system, thereby preventing the duplication of item C
26 from^{occurring} being occurred. Thus, the above-mentioned method

prevents data of any same item between the manager system
2 and the managed system from being transferred in a
duplicated manner, thereby enhancing the efficiency of the
4 data transfer.

Embodiment 2:

6 The processing to be performed is ^{carried out} generally in the
same manner as that of the embodiment 1, except for the
8 implementation method and merge-process. Therefore, the
following describes mainly Merger-Process with reference to
10 the state transition diagrams shown in FIGS. 18 and 19 and
the flowchart shown in FIG. 20. The other processing will
12 be described only ^{for those} ^{which are} in the portions different from those of
the embodiment 1. Now, referring to FIG. 18, this system
14 attaches an operation flag to each item to be downloaded.
To this operation flag indicating ^{the} operation status, either
16 "A" indicative of addition or "D" indicative of deletion is
set (1805).

18 The upper manager system stores the information
edited in ^{the} edit-process of items (processing for storing
20 operation history is added behind each operation processing
described in the flowcharts shown in FIGS. 10 and 11) and
22 adds the operation flag to each item in the item file
(1805) to be downloaded upon completion of edit-process
24 (only the items manipulated in S304 of FIG. 10 are
extracted and item adding processing is performed for the
item preparing processing).

As shown in FIG. 18, if items are added, "A" is
2 attached to item D and item X to be added and "D" is
attached to item A to be deleted. First, referring to FIG.
4 20, when the item file is downloaded from the upper manager
system in ^adownload-waiting state (S201), this system reads
6 the operation flag and its item (S202). If the operation
flag is deletion ("D") and the attribute of this item is
8 the item managed by ^{the}upper system ("1"), this system deletes
the item from the DB and reads ^{the}[a]next item (S204, S205,
10 S208, A).

If the operation flag is deletion ("D") and the
12 attribute is the common item ("2"), this system changes the
attribute from the common item to the item managed by this
14 system ("0") and reads ^{the}[a]next item (step S204, S205, S206,
S209, A). If the operation flag is addition ("A") and
16 there is no item, this system adds an item to the DB, sets
the attributes of this item to the item managed by ^{the}upper
18 system ("1"), and reads ^{the}(a)next item (S204, S210, S212, A).

If the operation flag is addition ("A") and the
20 attribute of the item existing in this system is ^{an}(the) item
managed by this system ("0"), this system sets the
22 attribute of this item to the common item ("2") and reads ^{the}[a]next
next item (S204, S210, S211, S213, A). Then, for the other
24 combinations of statuses than those mentioned above, this
system does nothing but reading ^{the}(a)next item (A).

Having read all items, this system downloads the

item file that was received from the upper manager system
2 to all the submanager systems and managed systems in the
lower layer connected thereto without change (S207) and
4 waits for the downloading of another item file from the
upper manager system (S207 to C).

6 This series of processing operations results in a
table whose status^{is} shown in FIG. 19. FIG. 19 shows that
8 item A deleted by the upper manager system and item D and
item X added by the upper manager system are downloaded,
10 the downloaded items are merged with the items held in the
lower manager system, item D is newly added as the item
12 managed by^{the} upper system, and the attribute of item X is
changed to the common item.

14 Thus, the second embodiment prevents^{the} [a] same item
from being transferred in a duplicated manner and requires
16 only a constant size of the item file to be downloaded
which is a difference equivalent to the change made to the
18 file.

Embodiment 3:

20 In the embodiment 1 and the embodiment 2, the same
items are managed by use of attribute information in each
22 manager system. In the embodiment 3, each manager system
has only the items that are managed by this system (on its
24 own) only and has no attribute information, and each of the
managed systems holds a requirement system (the program
configuration for the embodiment 3 is the same as that of

the embodiment 1).

First, ^{the} merge-process will be described with reference to the flowchart shown in FIG. 24 and the status transition diagrams shown in FIGS. 22 and 23. It is assumed that the following description is made with reference to the lower manager system shown in these transition diagrams. In the initial state, this system is waiting for the downloading from the upper manager system or the manager system (S401).

The states of the items in the DB of each manager system are as shown in FIG. 22. For the system names, "SYSTEM" is set to the upper manager system and "SITE" to this lower manager system. The upper system holds items A, B, and C and this system holds items C, D, and E.

Each item file to be downloaded is composed of items and manager system names for managing these items as shown in FIG. 23. When an item file 1 (2305) has been downloaded from the upper manager system to this system in the download-waiting state (S401), this system reads an item and its manager system name from the downloaded file (S402).

If the read item is found also in the items managed by this system (S404), this system adds the name of this system as a manager system to the duplicating name and its manager system name and writes the result to an item file 2 (2307) to be downloaded to the lower-layer system (S408). If no duplicating item is found, this system writes the

items and their manager system names to the item file 2
(2307) without change, to be downloaded to the lower-layer
system (S405). Having read all items (S403), this system
extracts the items managed by this system that are not
^{duplicates}
[duplicating], adds the name of this system to each of these
items as the manager system name, writes these items to the
item file 2 (2307) to be downloaded to the lower-layer
system (S406), downloads the prepared item file 2 (2307) to
the lower-layer system (S407), and waits for the
downloading of the item file 1 (2305) from the upper
manager system (S401).

FIG. 23 shows the downloading of the item files.

Because item C is duplicated in both the upper [manager] ^{manager}
system (SYSTEM) and the lower manager system (SITE), system
names "SYSTEM" and "SITE" are set as manager system names.

Each managed system holds the item file in the form of an
item file to be downloaded (in other words, the managed
system holds the information about which item is to be
returned to which manager system).

When property information has been inputted at the
managed system, a result file is prepared in combinations
of item, property information, and manager system name.

The prepared result file is uploaded to the upper system of
the managed system. The following describes ^{the} update-process
with reference to the flowchart shown in FIG. 26 and the
status transition diagram shown in FIG. 25.

In the initial state, this system (SITE) is waiting for the uploading of a result file 1 (2505)(SS01) from the system immediately below. When the result file 1 (2505) has been uploaded, this system opens it and reads the items, property information, and manager system names for one entry (S502).

If the name of this system is included in the manager system names of that entry (S504), this system updates the property information in its DB (S507), deleting the name of this system from the manager system names (S508). If another system name exists in the manager system names (S509), this system writes the entry with the name of this system removed to a result file 2 (2507) to be uploaded as a result file to its upper manager system (S505).

If the name of this system is not included in the read entry from the beginning, this system does not update the entry and writes the entry as it is to the result file 2 (2507) (S505). Upon reading all entries (S503), this system uploads the prepared result file 2 (2507) to its upper manager system (S506) and waits again until the result file 1 (2505) is uploaded from its lower-layer system (S501).

FIG. 25 shows the flow of the result files, in which property items A, B, C, D, and E are uploaded as a result from its lower-layer system and this system (SITE) updates

its DB with respect to items C, D, and E, uploading the
2 result file containing items A, B, and C to its upper
manager system (SYSTEM).

4 Because item C is common to this system and its
upper system, this system updates its DB and uploads the
6 result file, thereby preventing the duplication of item C
from occurring. It should be noted that ^{the} edit-process is
8 executed only to edit the items of this system and
therefore no special processing is executed. For this
10 reason, ^a ~~(the)~~ ^{the} description of ^{the} edit-process is skipped.

Thus, the embodiment 3 prevents the duplicated
12 transfer of items common to the manager system and the
managed system to realize efficient data transmission in a
14 method different from those of the embodiments 1 and 2.

Embodiment 4:

This embodiment, in addition to the capabilities of
embodiment 1, provides a capability of allowing each
submanager system to define in advance default items and
their property information. The following describes this
method with reference to FIGS. 27 through 29.

FIG. 27 shows the initial states of the manager
system and submanager systems in which the manager system
of the head office prepares items "business office code",
"department code", "name", "extension number", the
submanager system of the business office defines "business
office code" and the submanager system of the department

defines "department code" as defaults. Addition and ^{AA} deletion of default items can be executed as a part of ^A edit-process.

4 FIG. 28 shows a processing flow in which an item
file is downloaded to each system. An item file (2805) is
6 downloaded from the manager system of the head office to
the submanager system of the business office. The
8 submanager system of the business office compares the item
names in the item file with the default item names. If a
10 matching name is found, the submanager system stores the
matching item and its property information into the default
12 DB. Then, the submanager system of the business office
downloads an item file (2808) ^{composed} of "department code," "name",
14 and "extension number" with "business office code" removed
therefrom to the submanager system of the department. The
submanager system of the department processes "department
code" in the same manner and downloads an item file (2811)
composed of "name" and "extension number" and sets property
information for that item. It should be noted that the
items and their property information stored in the default
DB are deleted when new items are downloaded from the upper
manager system.

FIG. 29 shows the processing flow in which result
files are uploaded. When property information is inputted
in the managed system, the managed system uploads a result
file to the submanager system of the department. The

submanager system of the department adds the item and
2 property information in the default DB to the result file
and uploads it to the submanager system of the business
4 office. The submanager system of the business office
carries out the same processing as described above,
6 uploading the result file to the manager system of the head
office, the result file storing the property information of
8 all items. The current embodiment can be actually
implemented by adding particular processing to the
10 processing flow of embodiment 1.

First, in ^{the}merge-process, this system adds processing
12 in which the contents of the default DB are all deleted
upon downloading of an item file (this processing is added
14 under S003 of FIG. 15). This system checks the downloaded
items for an default item. After entering property
16 information of the same time as the default item into the
default DB. This system adds processing in which no file
18 is downloaded to the lower-layer system (this processing is
added under S005 of FIG. 15). Then, when the information
20 is uploaded in ^{the}update-process, this system adds processing
in which the items and their default values are
22 additionally written to the result file to be uploaded to
the upper manager system (this processing is added so that
it is executed when the file has all been read in S103 of
FIG. 17). Thus, embodiment 4 can reduce the amount of data
transfer by the items defined by default.

Embodiment 5:

2 In embodiment 5, this system determines in the
method of embodiment 4 whether there is any default item in
4 the items downloaded by the submanager system to this
system. If a default item is found, this system enters the
6 property information of the same item into the default DB.
Then, if there is no more item to be downloaded to the
8 manager system or the managed system in ^{the} lower layer (if
this system has set the default items for all items), this
10 system extracts the items and property information from the
default DB, prepares a result file, and uploads it to the
12 upper manager system.

In the actual implementation method, embodiment 5
14 can be realized by adding particular processing to the flow
of embodiment 1 on which the capabilities of embodiment 4
16 are implemented. In ^{the} merge-process, this system determines
whether there is any item file which is downloaded to the
18 lower-layer manager system or the managed system. If such
an item file is found, this system downloads it. If no
20 such item file is found, this system adds processing in
which all contents of the default DB are extracted, a
22 result file is prepared to be uploaded to the upper manager
system, and [uploads] the prepared result file ^{is uploaded} to the upper
24 system (this processing is added under S008 of FIG. 15).

The method of embodiment 5 can prevent the data
transfer from the submanager system which has completed the

input of property information by items defined by default
✓ to the managed system.

In addition, this method enhances the efficiency of
✓ data transfer over one route of ^{the} network in a hierarchical
network environment, which in turn ^{achieves} [realizing the] efficient
✓ data transfer over the entire network.

While the preferred embodiments of the present
✓ invention have been described using specific terms, such
description is for illustrative purposes only, and it is to
✓ be understood that changes and variations may be made
without departing from the spirit or scope of the appended
claims.
